# **Chapter 7: Deadlocks**

### **Chapter 7: Deadlocks**

- System Model
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

### **Chapter Objectives**

- To develop a description of deadlocks, which prevent sets of concurrent processes from completing their tasks
- To present a number of different methods for preventing or avoiding deadlocks in a computer system

### **System Model**

- System consists of resources
- □ Resource types  $R_1, R_2, ..., R_m$ CPU cycles, memory space, I/O devices
- □ Each resource type  $R_i$  has  $W_i$  instances.
- Each process utilizes a resource as follows:
  - request
  - use
  - release

#### **Deadlock Characterization**

Deadlock can arise if four conditions hold simultaneously.

- Mutual exclusion: only one process at a time can use a resource
- Hold and wait: a process holding at least one resource is waiting to acquire additional resources held by other processes
- No preemption: a resource can be released only voluntarily by the process holding it, after that process has completed its task
- Circular wait: there exists a set  $\{P_0, P_1, ..., P_n\}$  of waiting processes such that  $P_0$  is waiting for a resource that is held by  $P_1, P_1$  is waiting for a resource that is held by  $P_2, ..., P_{n-1}$  is waiting for a resource that is held by  $P_n$ , and  $P_n$  is waiting for a resource that is held by  $P_0$ .

#### **Deadlock with Mutex Locks**

- Deadlocks can occur via system calls, locking, etc.
- ☐ See example box in text page 318 for mutex deadlock

### **Resource-Allocation Graph**

A set of vertices V and a set of edges E.

- V is partitioned into two types:
  - $P = \{P_1, P_2, ..., P_n\}$ , the set consisting of all the processes in the system
  - $R = \{R_1, R_2, ..., R_m\}$ , the set consisting of all resource types in the system
- □ request edge directed edge  $P_i \rightarrow R_i$
- □ assignment edge directed edge  $R_j \rightarrow P_i$

### Resource-Allocation Graph (Cont.)

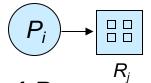

Process

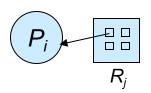

Resource Type with 4 instances

 $\square$   $P_i$  requests instance of  $R_i$ 

 $\square$   $P_i$  is holding an instance of  $R_j$ 

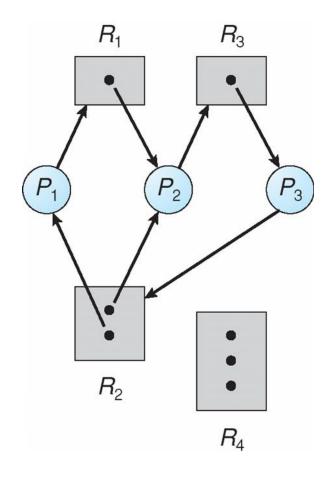

#### **Example of a Resource Allocation Graph**

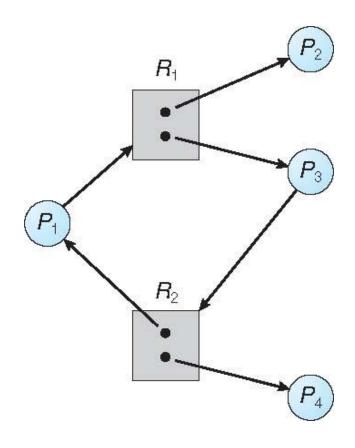

## **Resource Allocation Graph With A Deadlock**

## **Graph With A Cycle But No Deadlock**

#### **Basic Facts**

- □ If graph contains no cycles  $\Rightarrow$  no deadlock
- ☐ If graph contains a cycle ⇒
  - if only one instance per resource type, then deadlock
  - if several instances per resource type, possibility of deadlock

### **Methods for Handling Deadlocks**

- Ensure that the system will never enter a deadlock state:
  - Deadlock prevention
  - Deadlock avoidence
- Allow the system to enter a deadlock state and then recover
- Ignore the problem and pretend that deadlocks never occur in the system; used by most operating systems, including UNIX

#### **Deadlock Prevention**

#### Restrain the ways request can be made

- Mutual Exclusion not required for sharable resources
  (e.g., read-only files); must hold for non-sharable resources
- □ Hold and Wait must guarantee that whenever a process requests a resource, it does not hold any other resources
  - Require process to request and be allocated all its resources before it begins execution, or allow process to request resources only when the process has none allocated to it.
  - Low resource utilization; starvation possible

### **Deadlock Prevention (Cont.)**

#### ■ No Preemption –

- If a process that is holding some resources requests another resource that cannot be immediately allocated to it, then all resources currently being held are released
- Preempted resources are added to the list of resources for which the process is waiting
- Process will be restarted only when it can regain its old resources, as well as the new ones that it is requesting
- □ Circular Wait impose a total ordering of all resource types, and require that each process requests resources in an increasing order of enumeration

#### **Deadlock Avoidance**

Requires that the system has some additional *a priori* information available

- Simplest and most useful model requires that each process declare the *maximum number* of resources of each type that it may need
- The deadlock-avoidance algorithm dynamically examines the resource-allocation state to ensure that there can never be a circular-wait condition
- Resource-allocation state is defined by the number of available and allocated resources, and the maximum demands of the processes

#### **Safe State**

- When a process requests an available resource, system must decide if immediate allocation leaves the system in a safe state
- System is in safe state if there exists a sequence  $\langle P_1, P_2, ..., P_n \rangle$  of ALL the processes in the systems such that for each  $P_i$ , the resources that  $P_i$  can still request can be satisfied by currently available resources + resources held by all the  $P_i$ , with j < I
- That is:
  - If P<sub>i</sub> resource needs are not immediately available, then P<sub>i</sub> can wait until all P<sub>i</sub> have finished
  - Uhen  $P_j$  is finished,  $P_i$  can obtain needed resources, execute, return allocated resources, and terminate
  - When  $P_i$  terminates,  $P_{i+1}$  can obtain its needed resources, and so on

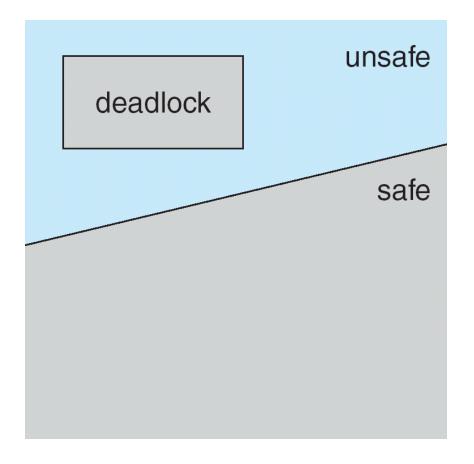

### **Basic Facts**

- □ If a system is in safe state ⇒ no deadlocks
- ☐ If a system is in unsafe state ⇒ possibility of deadlock
- □ Avoidance ⇒ ensure that a system will never enter an unsafe state.

### Safe, Unsafe, Deadlock State

### **Avoidance Algorithms**

- Single instance of a resource type
  - Use a resource-allocation graph
- Multiple instances of a resource type
  - Use the banker's algorithm

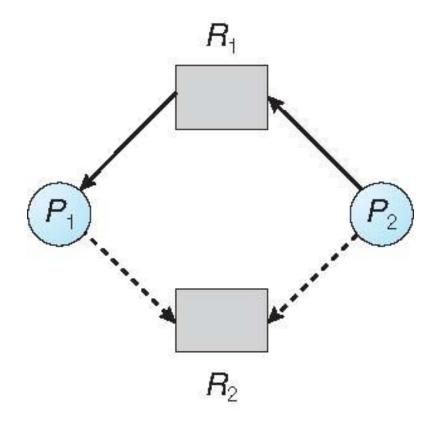

### **Resource-Allocation Graph Scheme**

- □ Claim edge  $P_i \rightarrow R_j$  indicated that process  $P_j$  may request resource  $R_i$ ; represented by a dashed line
- Claim edge converts to request edge when a process requests a resource
- Request edge converted to an assignment edge when the resource is allocated to the process
- When a resource is released by a process, assignment edge reconverts to a claim edge
- Resources must be claimed a priori in the system

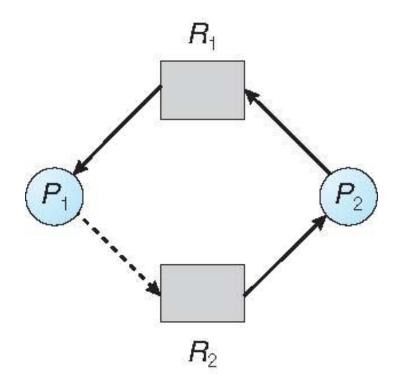

#### **Resource-Allocation Graph**

### **Unsafe State In Resource-Allocation Graph**

#### **Resource-Allocation Graph Algorithm**

- $\square$  Suppose that process  $P_i$  requests a resource  $R_i$
- The request can be granted only if converting the request edge to an assignment edge does not result in the formation of a cycle in the resource allocation graph

### **Banker's Algorithm**

- Multiple instances
- Each process must a priori claim maximum use
- When a process requests a resource it may have to wait
- When a process gets all its resources it must return them in a finite amount of time

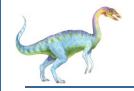

#### Data Structures for the Banker's Algorithm

Let n = number of processes, and m = number of resources types.

- □ **Available**: Vector of length m. If available [j] = k, there are k instances of resource type  $R_i$  available
- □ **Max**:  $n \times m$  matrix. If Max[i,j] = k, then process  $P_i$  may request at most k instances of resource type  $R_j$
- □ **Allocation**:  $n \times m$  matrix. If Allocation[i,j] = k then  $P_i$  is currently allocated k instances of  $R_j$
- **Need**:  $n \times m$  matrix. If Need[i,j] = k, then  $P_i$  may need k more instances of  $R_i$  to complete its task

$$Need[i,j] = Max[i,j] - Allocation[i,j]$$

### Safety Algorithm

1. Let **Work** and **Finish** be vectors of length *m* and *n*, respectively. Initialize:

Work = Available  
Finish 
$$[i]$$
 = false for  $i = 0, 1, ..., n-1$ 

- 2. Find an *i* such that both:
  - (a) Finish [i] = false
  - (b)  $Need_i \leq Work$ If no such i exists, go to step 4
- 3. Work = Work + Allocation; Finish[i] = true go to step 2
- 4. If *Finish* [*i*] == *true* for all *i*, then the system is in a safe state

### Resource-Request Algorithm for Process $P_i$

 $Request_i = request \ vector for process P_i$ . If  $Request_i [j] = k$  then process  $P_i$  wants k instances of resource type  $R_j$ 

- If *Request<sub>i</sub>* ≤ *Need<sub>i</sub>* go to step 2. Otherwise, raise error condition, since process has exceeded its maximum claim
- 2. If  $Request_i \leq Available$ , go to step 3. Otherwise  $P_i$  must wait, since resources are not available
- 3. Pretend to allocate requested resources to  $P_i$  by modifying the state as follows:

Available = Available - Request<sub>i</sub>; Allocation<sub>i</sub> = Allocation<sub>i</sub> + Request<sub>i</sub>; Need<sub>i</sub> = Need<sub>i</sub> - Request<sub>i</sub>;

- □ If safe  $\Rightarrow$  the resources are allocated to  $P_i$
- ☐ If unsafe  $\Rightarrow$   $P_i$  must wait, and the old resource-allocation state is restored

## **Example of Banker's Algorithm**

 $\square$  5 processes  $P_0$  through  $P_4$ ;

3 resource types:

A (10 instances), B (5instances), and C (7 instances)

Snapshot at time  $T_0$ :

	<u>Allocation</u>	<u>Max</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	010	753	332
$P_1$	200	322	
$P_2$	302	902	
$P_3$	211	222	
$P_4$	002	433	

### **Example (Cont.)**

☐ The content of the matrix *Need* is defined to be *Max – Allocation* 

	<u>Need</u>	
	ABC	
$P_0$	7 4 3	
$P_1$	122	
$P_2$	600	
$P_3$	0 1 1	
$P_4$	4 3 1	

The system is in a safe state since the sequence  $< P_1, P_3, P_4, P_2, P_0 >$  satisfies safety criteria

### Example: $P_1$ Request (1,0,2)

☐ Check that Request  $\leq$  Available (that is,  $(1,0,2) \leq (3,3,2) \Rightarrow$  true

	<u>Allocation</u>	<u>Need</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	010	7 4 3	230
$P_1$	302	020	
$P_2$	302	600	
$P_3$	211	0 1 1	
$P_4$	002	4 3 1	

- Executing safety algorithm shows that sequence  $< P_1, P_3, P_4, P_0, P_2 >$  satisfies safety requirement
- $\square$  Can request for (3,3,0) by  $P_4$  be granted?
- $\square$  Can request for (0,2,0) by  $P_0$  be granted?

# **End of Chapter 7**
